

ABSTRACT

A process for staging file assets on a live Web server is described that includes detecting an index page of the Web server, creating a staging folder on the Web server, wherein the staging folder does not default to a directory listing when accessed, inserting a randomized string into a name of file assets containing content to be staged, and storing the file assets in the staging folder. By creating the staging folder that does not default to a directory listing when accessed, a system is enabled where users may access the file assets while other users may not.
